Abstract

The integration of wind farms into the electricity grid has become an important challenge for the utilization and control of electric power systems, because of the fluctuating and intermittent behavior of wind power generation. Doubly fed induction generators (DFIG) are commonly used wind turbine generators (WTG) in electricity networks. In DFIG there are three control loops which should be implemented in order to appropriate performance of WTG. These control loops are pitch angle control, rotor speed control and voltage control. In this paper a unified scheme is used to adjust these controllers in the same time. Particle Swarm Optimization (PSO) is used to adjustment the proposed controllers. The results of wind power on the system performance are compared with a conventional thermal power plant.

Keywords: Wind Turbine Generators; Doubly Fed Induction Generators; Pitch Angle Control; Multi Machine Electric Power System; Particle Swarm Optimization.

Introduction

Wind turbines generators (WTGs) are usually controlled to generate maximum electrical power from wind under normal wind conditions. However, because of the variations of the wind speed, the generated electrical power of a WTG is usually fluctuated. Currently, wind energy only provides about 1%-2% of the U.S.'s electricity supply. At such a penetration level, it is not necessary to require WTGs to participate in automatic generation control, unit commitment, or frequency regulation.

In order to meet power needs, taking into account economical and environmental factors, wind energy conversion is gradually gaining interest as a suitable source of renewable energy. The electromagnetic conversion is usually achieved by induction machines or synchronous and permanent magnet generators. Squirrel cage induction generators are widely used because of their lower cost, reliability, construction and simplicity of maintenance (Heier, 1998). But when it is directly connected to a power network, which imposes the frequency, the speed must be set to a constant value by a mechanical device on the wind turbine. Then, for a high value of wind speed, the totality of the theoretical power cannot be extracted. To overcome this problem, a converter, which must be dimensioned for the totality of the power exchanged, can be placed between the stator and the network. In order to enable variable speed operations with a lower rated power converter, doubly-fed induction generator (DFIG) can be used as shown on Fig.1.

The stator is directly connected to the grid and the rotor is fed to magnetize the machine. Control of electrical power exchanged between the stator of the DFIG and the power network by controlling independently the torque (consequently the active power) and the reactive power is an important issue in DFIG utilization (Xu & Cheng, 1995). Several investigations have been developed in this direction using converters and classical proportional-integral regulators (Yamamoto & Motoyoshi, 1991; Rifai & Ortmeyer, 1993; Hopfensperger et al., 2000).

In this paper a unified scheme is used to adjust DFIG controllers in same time. Particle Swarm Optimization (PSO) (Mehdi Nikzad et al., 2011; Sayed Mojtaba Shirvani Boroujeni et al., 2011) is used to adjustment the proposed controllers. The results of wind power on the system performance are compared with a conventional thermal power plant.

Mathematical model of the DFIG

For a doubly fed induction machine, the Concordia and Park transformation's application to the traditional a,b,c model allows to write a dynamic model in a d-q reference frame as follows:
In DFIG there are three control loops which should be implemented in order to appropriate performance of wind farm. These control loops are pitch angle control, rotor speed control and voltage control. These control schemes are thoroughly explained in Fig.2-4. In this paper PSO is used to adjust proposed controllers.

**Particle swarm optimization**

PSO was formulated by Edward and Kennedy in 1995. The thought process behind the algorithm was inspired by the social behavior of animals, such as bird flocking or fish schooling. PSO is similar to the continuous GA in that it begins with a random population matrix. Unlike the GA, PSO has no evolution operators such as crossover and mutation. The rows in the matrix are called particles (same as the GA chromosome). They contain the variable values and are not binary encoded. Each particle moves about the cost surface with a velocity. The particles update their velocities and positions based on the local and global best solutions as shown in (2) and (3):

\[
V_{m,n}^{\text{new}} = wV_{m,n}^{\text{old}} + \Gamma_1 r_1 x(\text{P}_{m,n}^{\text{best local}} - \text{P}_{m,n}^{\text{old}}) + \Gamma_2 r_2 x(\text{P}_{m,n}^{\text{best global}} - \text{P}_{m,n}^{\text{old}})
\]

(2)

\[
P_{m,n}^{\text{new}} = P_{m,n}^{\text{old}} + \Gamma V_{m,n}^{\text{new}}
\]

(3)

Where:

- \(V_{m,n}\) = particle velocity
- \(P_{m,n}\) = particle variables
- \(w\) = inertia weight
- \(r_1, r_2\) = independent uniform random numbers
- \(\Gamma_1, \Gamma_2\) = learning factors
- \(\text{P}_{m,n}^{\text{best local}}\) = best local solution
- \(\text{P}_{m,n}^{\text{best global}}\) = best global solution

The PSO algorithm updates the velocity vector for each particle then adds that velocity to the particle position or values. Velocity updates are influenced by both the best global solution associated with the lowest cost ever found by a particle and the best local solution associated with the lowest cost in the present population. If the best local solution has a cost less than the cost of the current global solution, then the best local solution replaces the best global solution. The particle velocity is reminiscent of local minimas that use derivative information, because velocity is the derivative of position. The advantages of PSO are that it is easy to implement and there are few parameters to adjust. The PSO is able to tackle tough cost functions with many local minima (Randy & Sue, 2004).

**Illustrative test case**

In order to evaluate the effect of WTG on the system performance, a multi machine electric power system which is IEEE 14 bus test system is considered as case study (Milano, 2010). In the proposed test system two following cases...
are considered:
Case 1: power generator at bus 1 is a thermal power plant
Case 2: power generator at bus 1 is a wind turbine power plant
Both the cases are simulated and compared under disturbance. Fig.5 shows the proposed test system with a WTG installed in bus 1. Also in this paper the wind speed is modeled as Weibull Distribution (Milano, 2010).

Controllers adjustment using PSO

In this section the parameters of the proposed controllers are tuned using PSO. In optimization methods, the first step is to define a performance index for optimal search. In this study the performance index is considered as (4). In fact, the performance index is the Integral of the Time multiplied Absolute value of the Error (ITAE).

\[
ITAE = \int_0^T t|\Delta \omega_1|dt + \int_0^T t|\Delta \omega_2|dt + \int_0^T t|\Delta \omega_3|dt + \int_0^T t|\Delta \omega_4|dt + \int_0^T t|\Delta \omega_5|dt
\]

(4)

It is clear to understand that the controller with lower ITAE is better than the other controllers. To compute the optimum parameter values, a three phase short circuit is assumed at bus 4 and the performance index is minimized using PSO.

It should be noted that PSO algorithm is run several times and then optimal set of parameters is selected. The optimum values parameters are obtained using PSO and summarized in Table.1.
Results and discussions

The simulation results are carried out on the proposed test system with both the cases. Fig.6-10 show the results following a 12 cycle three phase short circuit is assumed at bus 14. It is clearly seen that WTG has a great effect on the system stability and increasing damping of oscillations. With WTG, in all figures the oscillations are damped out successfully and the transient and dynamic stability margin of the system is increased. Also, voltage of bus 2 is demonstrated in Fig.10. It is clearly seen that WTG not only has a great effect on system stability but also has a positive effect on the voltage of bus.

### Table 1. Optimum values of controllers

<table>
<thead>
<tr>
<th>Controller</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pitch angle gain</td>
<td>12.72</td>
</tr>
<tr>
<td>Pitch angle time constant</td>
<td>0.03</td>
</tr>
<tr>
<td>Voltage control gain</td>
<td>69.91</td>
</tr>
<tr>
<td>Power control time constant</td>
<td>0.015</td>
</tr>
</tbody>
</table>

**Conclusion**

A unified tuning of DFIG controllers successfully carried out in this paper. PSO used to adjust the DFIC controllers. The proposed DFIG was compared with conventional generators in thermal power plants. It showed that DFIG has a great effect on the system stability and performance. DFIG also successfully controlled the voltage. The paper showed that utilization of DFIG not only is suitable from view of energy and environmental effects, but also is appropriate from view of system stability and performance.
